1. Scope

This document describes how an application should use the Challenge Response API in the CSR µEnergy® firmware.

2. Introduction

The Challenge Response feature within the CSR μ Energy® firmware provides a level of protection against *Man in the Middle* (MITM) security attacks. In particular the feature protects against the scenario where neither the Master (BLE) nor the Slave (BLE) are within range of each other, but they are both within range of a third BLE device known as the *Man in the Middle*. The *Man in the Middle* relays the radio packets transmitted by the two devices to make it appear they are within range of each other.

Use of the Challenge Response feature is optional, however it is recommended in situations where protection is required against the above attack scenario.

Limitations of Use

The Challenge Response feature must be performed at times when no other application data transfer is taking place between the Master and the Slave.

The Challenge Response procedure should be performed over a link with a short connection interval to minimise the delay in receiving responses.

The Challenge Response procedure should be performed as soon as possible after connection establishment and link encryption.

The Master and Slave can repeat the Challenge Response procedure after connection establishment. Currently there are no known attack scenarios that require the procedure to be repeated.

4. Challenge Response Procedure

The Challenge Response procedure consists of the following sequence:

- 1. Establish an encrypted BLE link, see section 4.1
- 2. The Master application starts T_{MAX} , where T_{MAX} is the maximum duration for the procedure to complete, see section 4.2
- 3. The Master application instructs the Master side firmware to perform RX timing calculations, see section 4.3
- 4. The Master application transmits the Challenge 1 packet and starts application timer T₁, see section 4.4
- 5. The Slave calculates the response as soon as it receives the challenge. The firmware delays sending the response packet over the air until the next challenge is received, see section 4.5
- 6. T₁ expires and the Master application transmits the Challenge 2 packet
- 7. When the Slave application receives Challenge 2 it instructs the Slave side firmware to resume normal transmission behaviour, i.e. data transmissions are no longer delayed until further packets are received, see section 4.7
- 8. The Master side firmware invokes the Master application's LM Event Handler, see section 4.8
- 9. The Master application instructs the Master side firmware to cease performing RX timing calculations, see section 4.9

 The Master application determines if the Challenge Response procedure was successful, see section 4.9

These steps are described more fully in the following sub sections.

Two sequence diagrams for the procedure are illustrated below; one demonstrates the Master as the Server, the other demonstrates the Master as the Client.

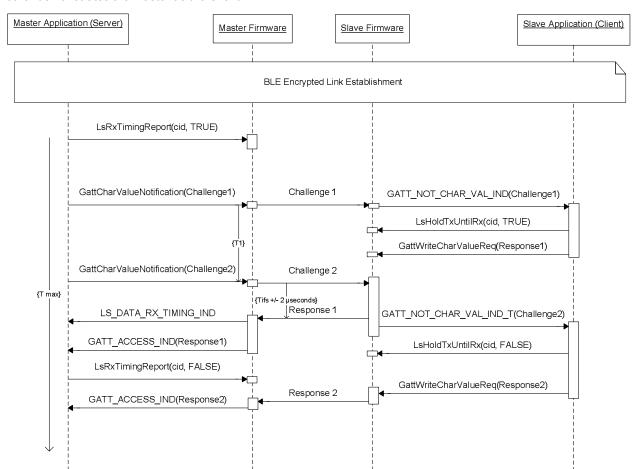

Figure 4.1: Challenge Response Procedure with the Master as the Server

Notes:

- The Application will regard the Challenge Response procedure as having failed if it has not completed before T_{MAX} expires.
- T₁ is the time period that the Master application waits between sending Challenge 1 and Challenge
 2.
- T_{IFS} is the minimum duration between the Master application sending Challenge 2 and receiving Response 1, T_{IFS} shall be 150 microseconds, see *Bluetooth Core Specification v4.0*.

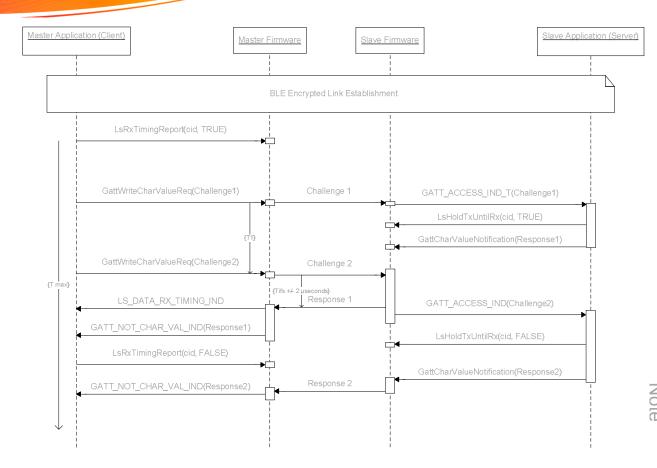

Figure 4.2: Challenge Response Procedure with the Master as the Client

Notes:

- The Application will regard the Challenge Response procedure as having failed if it has not completed before T_{MAX} expires.
- T₁ is the time period that the Master application waits between sending Challenge 1 and Challenge
 2.
- T_{IFS} is the minimum duration between the Master application sending Challenge 2 and receiving Response 1, T_{IFS} shall be 150 microseconds, see *Bluetooth Core Specification v4.0*.

4.1. Establish an Encrypted BLE Link

An encrypted link is established using one of the mechanisms available for BLE link encryption e.g. Just Works or Passkey Entry, see *Bluetooth Core Specification v4.0*.

4.2. Maximum Challenge Response Procedure Duration: T_{MAX}

The maximum duration of the Challenge Response Procedure (T_{MAX}) is application specific. If the Master application has not received and processed the LS_DATA_RX_TIMING_IND within this period then the procedure has failed and the Master application must instruct the firmware to cease performing measurement calculations as described in section 4.9.

If the Slave application has not received Challenge 2 when T_{MAX} has expired then the Slave application must instruct the firmware to cancel the hold on data transmissions.

4.3. Instruct the BLE Firmware to Perform RX Timing Calculations

Instruct the BLE firmware to perform Challenge Response timing calculations by invoking LsRxTimingReport(cid, TRUE).

4.4. The Master Application Transmits a Challenge Packet

The Master application generates a Challenge packet which contains a maximum of 20 octets of data. The data within the Challenge packet should be changed in a non-predictable manner each time a Challenge packet is constructed to protect against replay attacks.

4.4.1. Transmit a Challenge when the Master Application is a GATT Client

If the Master application is in a client role then it transmits the Challenge packet by invoking GattWriteCharValueReq().

4.4.2. Transmit a Challenge when the Master Application is a GATT Server

If the Master application is in a server role then it transmits the Challenge packet by invoking GattCharValueNotification().

4.5. The Slave Delays All Data Transmission Until the Next Packet is Received

The Slave application instructs the firmware to delay transmission of all data packets until it receives the next packet. The Slave application does this by invoking

LsHoldTxUntilRx(cid, TRUE).

4.6. The Slave Application Responds to Received Challenges

The Slave application generates a Response packet for each received Challenge, the Response packet shall contain a maximum of 20 octets of data. The data within the Response packet is generated from the data received in the Challenge packet using a cryptographic mechanism known to both the Master and Slave.

4.6.1. Transmit a Response when the Slave Application is a GATT Client

If the Slave application is in a client role then it transmits the Response packet by invoking GattWriteCharValueReq().

4.6.2. Transmit a Response when the Slave Application is a GATT Server

If the Slave application is in a server role then it transmits the Response packet by invoking GattCharValueNotification().

4.7. The Slave Resumes Normal Transmission Behaviour

The Slave application instructs the firmware to resume normal transmission behaviour by invoking

LsHoldTxUntilRx(cid, FALSE).

4.8. Firmware Sends Packet Timing Data to Application

The application must handle the new LS_DATA_RX_TIMING_IND event. The application determines if the timing parameters in the LS_DATA_RX_TIMING_IND are within the limits specified in section 5.1.1.

4.9. Determining that the Challenge Response Procedure is Complete

The Challenge Response procedure is complete when any of the following conditions has occurred:

- 1. The Master application has received and processed the timing data contained in the $LS_DATA_RX_TIMING_IND$ event as described in section 5.1.1.
- 2. The Master application has terminated the Challenge Response procedure after T_{MAX} has expired.

If any of these conditions are satisfied, the Master application must call LsRxTimingReport(cid, FALSE) causing the timing measurement reports sent by the firmware to cease.

5. Application Supplied Functions

The Master and Slave applications must each provide and register an implementation of an LM event handler function.

The Master side BLE firmware invokes this function and provides the timing data associated with the Challenge Response procedure within an LS_DATA_RX_TIMING_IND_T structure. This function is not specific to the Challenge Response procedure; it is invoked by the firmware whenever any LM event occurs.

Note:

This function is also used by the Slave application, however the $LS_DATA_RX_TIMING_IND$ event is never sent to the Slave application.

The Master and Slave applications must each define a customised service with characteristics for registering notifications and write procedures. The applications use these services to manage the Challenge Response procedure.

5.1. LM Event Handler Function

5.1.1. LS DATA RX TIMING IND

The firmware invokes the registered LM Event Handler Function and supplies a valid event code using the lm event code parameter and a valid pointer to an LM EVENT I type using the event data parameter.

If the lm_event_code is $LS_DATA_RX_TIMING_IND$ then the $event_data$ points to an $LS_DATA_RX_TIMING_IND_T$ structure, i.e. the $event_data$ should be cast to a (LS_DATA_RX_TIMING_IND_T*).

The ${\tt LS_DATA_RX_TIMING_IND_T}$ contains the following fields:

- time16 tx_duration: the duration in microseconds of the most recent packet transmission preceding the currently received packet,
- time48 tx_event_offset: the offset in microseconds of the most recent packet transmission within the current connection event,

• time48 tx_transmit_offset: the offset in microseconds of the most recent transmission from first possible transmit opportunity.

When performing the Challenge Response procedure the Master application must verify that these values are within the specified limits. If any value is outside of these limits then the Challenge Response procedure has failed and the Master application must take appropriate action. The specified limits are:

- tx duration must be greater than 80 microseconds.
- tx_event_offset must be less than or equal to 2 microseconds.
- tx_transmit_offset must be less than or equal to 2 microseconds
